Insight from top 5 papers

Climate change has significant impacts on biodiversity. It directly affects the growth and behavior of species, modifies their habitats, population size, composition, interactions, timing of reproduction, reproductive phenology, and growing season [1]. The increase in average global temperature and extreme weather events are common manifestations of climate change, leading to a decrease in crop productivity and loss of biodiversity [2]. Polar environments, which are high species richness areas, are particularly vulnerable to climate change, with increasing temperatures and other human impacts causing significant effects on polar biodiversity [3]. The rise in global temperatures and changes in precipitation patterns also contribute to increased biodiversity loss [4]. Mitigation measures, such as reducing greenhouse gas emissions and increasing forest cover, are essential to sustain biodiversity and human welfare [5]. Overall, climate change poses a serious threat to biodiversity and requires urgent action to minimize its negative impacts.
